This is a [step by step](#) tutorial on how to [install](#) and [configure](#) DNS server for your LAN using bind9. The DNS server will provide caching and name resolution as well as reverse name resolution for your local network. In this tutorial, we will use the domain "debian.lan" and this will be the domain of your local network. The domain "debian.lan" is not accessible from the internet; its private ip address is "192.168.100.1".

Installing bind9 and dns utilities

I assume that you already have a working Debian Etch or Ubuntu 8.04 [installation](#). Lets install the bind9 package and dns utilities from Debian repository.

```
apt-get install bind9 dnsutils
```

Configure your Linux system

Add this information to your `/etc/hostname`

```
echo "main.debian.lan" > /etc/hostname
```

Edit your `/etc/hosts`

```
127.0.0.1      localhost.localdomain  localhost
192.168.100.1  main.debian.lan main
# The following lines are desirable for IPv6 capable hosts
::1          ip6-localhost ip6-loopback
fe00::0      ip6-localnet
ff00::0      ip6-mcastprefix
ff02::1      ip6-allnodes
ff02::2      ip6-allrouters
ff02::3      ip6-allhosts
```

Edit your `/etc/resolv.conf`

```
vi /etc/resolv.conf
```

and add this information.

```
search debian.lan
nameserver 127.0.0.1
nameserver 192.168.100.1
```

```
nameserver xxx.xxx.xxx.xxx
nameserver xxx.xxx.xxx.xxx
```

This is where Linux looks to find out how it should perform DNS lookups.

Lets create a zone

The zone files (or database files) are the heart of your BIND system. This is where all the information is stored on what hostname goes with what ip address.

Before we create a zone [file](#), lets edit first the local configuration file `/etc/bind/named.conf.local`.

```
vi /etc/bind/named.conf.local
```

and the zone file data.

```
//
// Do any local configuration here
//

// Consider adding the 1918 zones here, if they are not used in y
// organization
//include "/etc/bind/zones.rfc1918";

zone "debian.lan" {
    type master;
    file "db.debian.lan";
};

zone "100.168.192.in-addr.arpa" {
    type master;
    file "db.192.168.100";
};
```

Lets start creating a zone file in `/var/cache/bind/` directory. Create a file called `db.debian.lan`

```
vi /var/cache/bind/db.debian.lan
```

And add the following entry

```
$TTL 604800
@ IN SOA main.debian.lan. admin.debian.lan. (
    2008080101      ;serial
    04800           ;refresh
    86400           ;retry
    2419200         ;expire
    604800          ;negative cache TTL
)

@      IN      NS      main.debian.lan.
@      IN      A       192.168.100.1
@      IN      MX      10      main.debian.lan.
main   IN      A       192.168.100.1
www    IN      CNAME   main
ubuntu IN      A       192.168.100.2
```

Lets create the reverse DNS zone file called `db.192.168.100`

```
vi /var/cache/bind/db.192.168.100
```

and the the following entry.

```
$TTL 604800
@ IN SOA main.debian.lan. admin.debian.lan. (
    2008080101      ;serial
    604800          ;refresh
    86400           ;retry
    2419200         ;expire
    604800          ;negative cache TTL
)

@      IN      NS      main.debian.lan.
@      IN      A       192.168.100.1
1      IN      PTR     main.debian.lan.
2      IN      PTR     ubuntu.debian.lan.
```

The zone files are created, you can [check](#) your zone file configurations using these utilities:

```
named-checkzone main.debian.lan /var/cache/bind/db.debian.lan
named-checkconf /etc/bind/named.conf.local
```

Lets edit the file `/etc/bind/named.conf.options`

```
vi /etc/bind/named.conf.options
```

Uncomment the line `forwarders` and add your ISP's DNS server.

```
forwarders {
    202.78.97.41;
    202.78.97.3;
};
```

Lets restart our DNS server, and test using the tool `dig`.

```
/etc/init.d/bind9 restart
dig debian.lan
```

You should see the following message

```
; <<>> DiG 9.3.4 <<>> debian.lan
;; global options: printcmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 54950
;; flags: qr aa rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIO

;; QUESTION SECTION:
;debian.lan.                IN      A

;; ANSWER SECTION:
debian.lan.                64800   IN      A      192.168.100.1

;; AUTHORITY SECTION:
debian.lan.                64800   IN      NS      main.debian.lan.

;; ADDITIONAL SECTION:
main.debian.lan.          64800   IN      A      192.168.100.1

;; Query time: 1 msec
;; SERVER: 192.168.100.1#53(192.168.100.1)
;; WHEN: Tue Aug  5 09:33:40 2008
;; MSG SIZE rcvd: 79
```

Test your reverse DNS

```
dig -x debian.lan
```

If you see this message, you have [successfully installed](#) the DNS server.

```
; <<>> DiG 9.3.4 <<>> -x debian.lan
;; global options: printcmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NXDOMAIN, id: 42510
;; flags: qr rd ra; QUERY: 1, ANSWER: 0, AUTHORITY: 1, ADDITIONAL

;; QUESTION SECTION:
;lan.debian.in-addr.arpa.   IN      PTR

;; AUTHORITY SECTION:
in-addr.arpa.              10800   IN      SOA      A.ROOT-SERVERS.NE

;; Query time: 952 msec
;; SERVER: 192.168.100.1#53(192.168.100.1)
;; WHEN: Tue Aug  5 09:34:25 2008
;; MSG SIZE rcvd: 108
```

You can also check your DNS `nslookup` and `host` command.

```
nslookup debian.lan
nslookup 192.168.100.1
```

```
host debian.lan
host 192.168.0.1
```

All computers in the LAN are going to use 192.168.100.1 as a nameserver, this can be set manually by setting statically:

```
vi /etc/resolv.conf
```

then put this information.

```
nameserver 192.168.100.1
```

Have fun!
